

SOM2IF15 – Compilation

Introduction

Frédéric Loulergue

UNIVERSITE D'ORLEANS

2022

What is a Compiler?

A compiler is

a program that transforms a text written in a source language into a text written in a target language.

Examples

- ▶ javac, gcc, ocamlc, ocamlc, ...
- ▶ latex, dot
- ▶ Code generation from UML models
- ▶ Program extraction from formal proofs (Coq, Isabelle)

SOM2IF15

We are interested in **programming** languages

Let's compile a few programs

Demo

- ▶ `gcc`
- ▶ `javac`

Compilers: a vast area

- ▶ numerous source languages
- ▶ numerous target languages
- ▶ automata theory
- ▶ formal semantics
- ▶ algorithms (data structures, graphs, ...)
- ▶ hardware architecture
- ▶ software architecture
- ▶ ...

Compilers: a vast area

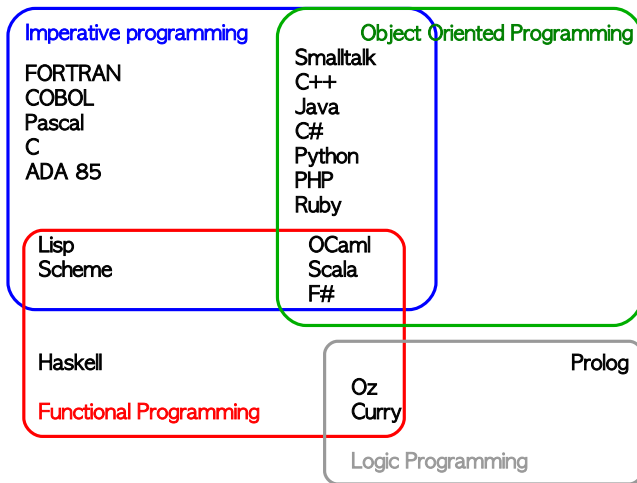

- ▶ numerous source languages
- ▶ numerous target languages
- ▶ automata theory
- ▶ formal semantics
- ▶ algorithms (data structures, graphs, ...)
- ▶ hardware architecture
- ▶ software architecture
- ▶ ...

This Class

- ▶ Programming a compiler from A to Z
- ▶ Questions:
 - ▶ Source language?
 - ▶ Target language?

- 1 Source Languages
- 2 Compilation, interpretation, virtual machines
- 3 Target Languages

Programming Languages and Paradigms

LUO: An Imperative Programming Language

- Features to be defined together

- 1 Source Languages
- 2 Compilation, interpretation, virtual machines
- 3 Target Languages

Compilation and Execution

Interpretation

Byte-code Compilation and Virtual Machine

- 1 Source Languages
- 2 Compilation, interpretation, virtual machines
- 3 Target Languages**

Last Phases of Compilers

Object Files

- ▶ compiler produces assembly code
- ▶ transformed into machine code object by the assembler

Several object files are put together by the **linker** that establishes links with the system libraries to produce an executable file

ABI - Application Binary Interface

For a given *operating system* and a given *architecture* the ABI specifications include:

- ▶ data placement
- ▶ call conventions
- ▶ object file formats
- ▶ functions of the system libraries

Machine Code

CISC Processors – *Complex Instruction Set Computer*

- ▶ many complex instructions (variable sizes)
- ▶ few registers
- ▶ direct programming of the machine

RISC Processors – *Reduced Instruction Set Computer*

- ▶ small and regular instruction set
- ▶ many registers
- ▶ simplified and unified decoding
- ▶ not meant for direct programming

Examples of Byte-codes and Virtual Machines

- ▶ P-code
- ▶ Byte-code-octet OCaml
- ▶ Byte-octet Java and the *Java Virtual Machine*
- ▶ Byte-octet Dalvik and the DVM (Android)
- ▶ *Common Language Runtime*

Available specification, assemblers

Native-code/Byte-code Compilation, Interpretation?

Comparison

Interpreter:

- ✓ easy to implement, to test, better interaction
- ✗ memory usage, execution speed

Compiler:

- ✓ memory usage, execution speed, error detection, optimization
- ✗ more complex, less flexible
- ▶ native-code: complex but efficient, less portable
- ▶ byte-code: less efficient, more portable, virtual machine to design and implement

- ▶ Compiler to (almost) native code
- ▶ Interpreter
- ▶ RISC processor: MIPS
- ▶ The SPIM simulator:
 - ▶ Direct execution of assembly code
 - ▶ Without the need of a operating system
 - ▶ Very small system library for basic input/output
